TTK29 Project description

For the project I am comparing different hybrid models' performance in learning/representing the blood oxygenated level dependent signal in the brain when some stimulus is applied. On modeling the BOLD signal there is quite a lot of literature available on a pure physical model, and there has been quite a lot of work on using PINNs as well. In addition to this I am also comparing CoSTA performance.

I am using the fMRI data from my project thesis, and will also be applying optimal sensor theory to try to find a minimal amount of sensors that could have been used to obtain the same measurements.
